Motives with small conductor

David P. Roberts
University of Minnesota, Morris

November 19, 2015
1. Small conductor problems

2. The explicit formula and lower bounds on conductors

3. The smallest conductors coming from special hypergeometric motives in low degree

4. A motive $M = M_6 \oplus M_8$ of particularly small conductor
1. Small conductor problems

Here are some important sequences:

1. Conductors of isogeny classes of elliptic curves are 11, 14, 15, 17, 19, 20, 21, 24, 26, 26, . . .

2. Levels of weight two newforms on $\Gamma_0$ are 11, 14, 15, 17, 19, 20, 21, 23, 23, 24, 26, 26, . . .

3. Levels of weight four newforms on $\Gamma_0$ are 5, 6, 7, 8, 9, 10, 11, 11, 12, . . .

4. Conductors of L-functions looking like they come from abelian surfaces with Sato-Tate group $Sp_4$ are 249, 277, 295, 349, 353, 388, 389, 394, . . . (Farmer-Koutsoliotas)

5. Paramodular levels of rational degree two Siegel eigenforms with Sato-Tate group $Sp_4$ in weight three: 61, 73, 79, . . . (Ash-Gunnells-McConnell; Poor-Yuen)
We would like to discuss similar sequences in a very broad context. To do this in a clean way, we will assume the fundamental and widely believed conjecture relating motives, L-functions, and automorphic forms, centering on $L(s, M) = L(s, \pi)$.

More precisely, working in the analytic normalization, we assume that irreducible degree $d$ motives $M \in M(\mathbb{Q}, \mathbb{C})$ modulo Tate twisting, are in bijection with primitive Selberg class L-functions with real spectral parameters, and these come bijectively from cuspidal automorphic representations $\pi$ of $GL_d(\mathbb{A})$ with algebraic infinity type.
Since we are working in the analytic normalization, it is best to rewrite $h^{p,q}$ as $h^{p-q}$. We present Hodge numbers of a pure-parity motive $M$ as a Hodge vector: 

$$(h^{−w}, h^{2−w}, \ldots, h^{w-2}, h^w)$$

with $h^k = h^{-k}$. When the parity is even, we consider Hodge vectors as coming with a refinement $h^0 = h^{0+} + h^{0−}$.

The Gamma factor of $L(M, s)$ is then

$$\Gamma_\mathbb{R}(s)^{h^{0+}} \Gamma_\mathbb{R}(s + 1)^{h^{0−}} \prod_{k \geq 1} \Gamma_\mathbb{C}(s + \frac{k}{2})^{h^k}.$$ 

For simplicity, all our explicit examples will have odd parity and so there will be no $\Gamma_\mathbb{R}$ factors.
Sequences belonging to a fixed Hodge vector

As a catch-all, we have the sequence $s(h)$ of conductors of motives $M \in M(\mathbb{Q}, \mathbb{C})$ with Hodge vector $h$. We can consider variants, like demanding that coefficients be within say $\mathbb{Q}$ or $\mathbb{R}$, or demanding irreducibility, or demanding genericity of the Sato-Tate group. The five examples again:

1. $s_{\mathbb{Q}}(1, 1): 11, 14, 15, 17, 19, 20, 21, 24, 26, 26, \ldots$
2. $s_{\mathbb{R}}(1, 1): 11, 14, 15, 17, 19, 20, 21, 23, 23, 24, 26, 26, \ldots$
3. $s_{\mathbb{R}}(1, 0, 0, 1): 5, 6, 7, 8, 9, 10, 11, 11, 12, \ldots$
4. $s_{\mathbb{Q}}^{\text{gen}}(2, 2): 249, 277, 295, 349, 353, 388, 389, 394, \ldots$
5. $s_{\mathbb{Q}}^{\text{gen}}(1, 1, 1, 1): 61, 73, 79, \ldots$

The small conductor problem is to go as far as possible towards identifying initial segments of sequences $s_{E}^{\text{cond}}(h)$. When $h$ is at all complicated, at present this often means exhibiting motives that seem to have small conductor for their setting.
Bunched vs. spread out Hodge vectors

Algebraic geometry easily gives many motives $M$ for particular unimodal $h$:

<table>
<thead>
<tr>
<th>Degree</th>
<th>Curves in $\mathbb{P}^2$</th>
<th>Surfaces in $\mathbb{P}^3$</th>
<th>Three-folds in $\mathbb{P}^4$</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

Automorphic forms most directly contribute to sequences with spread out Hodge vectors, $(1, 0, 0, 0, 1, 0, 0, 1, 0, 0, 0, 1)$.

We have been spoiled by $h = (1, 1)$, where both approaches work well!

In general, we know very little about the sequences $s(h)$. E.g. is the sequence $s^{\text{irred}}(1, 0, 0, 2, 3, 3, 2, 0, 0, 1)$ non-empty?
In this section, we sketch the Guinand-Weil explicit formula as it appears in Mestre’s 1988 Compositio paper *Formules explicites et minorations de conducteurs de variétés algébriques*. Throughout, we assume the Riemann hypothesis for all L-functions. Without this assumption, the final lower bound obtained is considerably weaker.

Mestre emphasizes the Hodge vectors \((g, g)\) for abelian varieties and \((1, 0, \ldots, 0, 1)\) for modular forms. We emphasize here that one gets non-trivial lower bounds for quite general Hodge vectors \(h\).
The explicit formula

For any motive $M$ with real coefficients and an entire L-function, and any allowed test function $F$, the Hodge vector $h$, the conductor $N$, the analytic rank $r$, the Frobenius traces $c_{pe} = \text{Tr}(Fr_p^e|M)$, and the critical $1/2 + \gamma_k i$ in the upper half plane are related by

$$\log N = 2\pi r + 4\pi \sum_k \hat{F}(\gamma_k) + 2 \int_0^\infty \hat{F}(t) \sum_j h^j E_j(t) dt$$

$$+ 2 \sum_p \sum_e c_{pe} \frac{\log p}{p^{e/2}} F\left(\frac{\log p}{2\pi}\right).$$

Today we are thinking of this explicit formula as an infinite family of exact formulas for $\log N$ which can be used to get lower bounds on $\log N$. There are many other useful perspectives as well!
The Fourier transform and test functions

We require \( F(x) \) to be even, compactly supported with \( F(0) = 1 \), and have two continuous derivatives. Its Fourier transform is then

\[
\hat{F}(t) = \int_{-\infty}^{\infty} F(x) e^{-2\pi i x t} dx.
\]

Among many standard properties is the scaling property: the Fourier transform of \( F(x/z) \) is \( z\hat{F}(zt) \).

In this talk, we used only scaled versions of the Odlyzko function:

\[
F_{\text{Od}}(x) = \chi_{[-1,1]} \left( (1 - |x|) \cos(\pi x) + \frac{\sin |\pi x|}{\pi} \right), \quad \text{(in } C^2 \text{ but not } C^3\text{)}.
\]

Its Fourier transform is

\[
\hat{F}_{\text{Od}}(t) = \frac{8\cos^2(\pi t)}{\pi^2(1 - 4t^2)^2} \quad \text{(quartic decay at } \infty\text{)}.
\]

For scaling we use \( F_z(x) = F_{\text{Od}}(2\pi x / \log z) \).
One would like both $F$ and $\hat{F}$ to very localized, but this is impossible because of the uncertainty principle. $F_2$ and $F_{13}$:

$\hat{F}_2$ and $\hat{F}_{13}$:
Zero density functions

$h^j E_j(t)$ is “the negative of the part of the expected zero density due to the Hodge number $h^j$”. Using $\psi(s) = \Gamma'(s)/\Gamma(s)$,

$$E_{0+}(t) = \log \pi - \text{Re} \left( \psi \left( \frac{1}{4} + \frac{it}{2} \right) \right), \quad E_j(t) = 2 \log 2\pi - 2\text{Re} \left( \psi \left( \frac{1}{2} + \frac{j}{2} + it \right) \right),$$

$$E_{0-}(t) = \log \pi - \text{Re} \left( \psi \left( \frac{3}{4} + \frac{it}{2} \right) \right).$$

Graphs of $E_{0+}(t)$ over $E_{0-}(t)$ on the left and $(E_0(t)), E_1(t), E_2(t)$, and $E_3(t)$ on the right:
Combining the test and density functions

The quantity \( \nu_z(j) = 2 \int_0^\infty \hat{F}_z(t)E_j(t)dt \) appears in the explicit formula. Graphs of \( \nu_2(j) \), \( \nu_{13}(j) \), and \( \nu_\infty(j) \):

One has

\[
\begin{align*}
\nu_\infty(0) &= \log(8\pi e^\gamma) \approx \log(44.76) \approx 3.80, \\
\nu_\infty(0+) &= \log(8\pi e^{\gamma + \frac{\pi}{2}}) \approx \log(215.33) \approx 5.37.
\end{align*}
\]
**Theorem.** Let $M$ be a weight $w$ motive with $L(s, M)$ entire and satisfying the Riemann hypothesis.

Let $h = (h^{-w}, h^{2-w}, \ldots, h^{w-2}, h^w)$ be its analytically normalized Hodge vector and let $N$ be its conductor.

Let $z$ be such that $c_q \geq 0$ for $q < z$.

Define $N_{z,h} = \exp \left( \sum_j h^j \nu_z(j) \right)$. Then

$$N > N_{z,h}.$$  

The bound for $z = 2$ applies to all motives, the stronger bound for $z = 3$ applies to “half” the motives, etc.
Comparison with modular forms

In the rank two case, the sequence of conductors is known via modular forms. The first conductor $N_w$ coming from the first motive $M_w$ is only slightly more than the $2$-bound from the theorem.

<table>

</tr>
</tbody>
</table>

Using Serre’s improvement of the Hasse-Weil bound on $c_p$, Mestre increased $z$ from 2 to 3.78 and improved 5.64 to 10.32.
Comparison with a theorem of Zak

A recent theorem of Zak says that, in a very broad range, Hodge vectors of the middle cohomology of \((n - 1)\)-dimensional varieties are asymptotically proportional to the \(n^{th}\) row of the Eulerian triangle:

\[
\begin{array}{ccccccc}
1 \\
1 & 1 \\
1 & 4 & 1 \\
1 & 11 & 11 & 1 \\
1 & 26 & 66 & 26 & 1 \\
1 & 57 & 302 & 302 & 57 & 1 \\
\end{array}
\]

As a consequence the \(h^j\) are roughly Gaussian with standard deviation \(\sqrt{(n + 1)/12}\). This makes the Hodge numbers bunched enough that \(N_{2,h} > 1\) for \(n\) into the hundreds.
The theorem applies to reducible motives such as \( M = \sum_{j=1}^{11} h_j M_j \), where it can be fairly sharp, even for \( z = 2 \).

However for irreducible motives, the \( c_p \), which always have mean zero, also have standard deviation 1.

For large degree \( d \), this is much less variation than allowed by the Hasse-Weil bound \( |c_q| \leq d \).

Accordingly, for large degree \( d \) we expect that it is quite rare for \( N \) to be less than \( N_{\infty,h} \). Thus, especially for large degree \( d \), \( N_{\infty,h} \) provides some guidance when working with the sequence \( s(h) \).
3. Special HGMs with small conductor

One has many one-parameter families of hypergeometric motives $H(A, B, t)$, covering e.g. all Hodge vectors in degree $< 20$.

One cannot expect these families to contain anywhere near all motives for a given $h$, since the motives $H(A, B, t)$ tend very strongly to be very wildly ramified at small primes. Special HGMs, i.e. those with $t = 1$, are only ramified at small primes.

On the next three slides, we consider six odd-weight $h$ and look at the smallest conductors arising from special hypergeometric motives with motivic Galois group all of $GSp_d$. Currently, for a given $h$, it is hard to find motives with smaller conductor.

All analytic ranks are 0 and 1, and those with 1 are have conductors in italics. There are special HGMs with apparent analytic rank 2 and 3, but their conductors are larger.
Degree two special HGMs with small conductor

\[ h = (1, 1) \]

\[
\begin{array}{|c|c|c|}
\hline
N & a & b \\
\hline
5.6 & 2\text{-bound} & \\
11 & \text{actual } \mathbb{R}\text{-lowest} & \\
24 & [2, 2, 6] & [1, 1, 3] \\
48 & [4, 6] & [1, 1, 3] \\
50 & [10] & [1, 1, 2, 2] \\
54 & [3, 6] & [1, 1, 2, 2] \\
54 & [6, 6] & [1, 1, 2, 2] \\
72 & [2, 2, 6] & [1, 1, 4] \\
75 & [5] & [1, 1, 3] \\
96 & [4, 4] & [1, 1, 3] \\
125.2 & \text{\(\infty\)-marker} & \\
\hline
\end{array}
\]

\[ h = (1, 0, 0, 1) \]

\[
\begin{array}{|c|c|c|}
\hline
N & a & b \\
\hline
3.5 & 2\text{-bound} & \\
5 & \text{actual } \mathbb{R}\text{-lowest} & \\
6 & [2, 2, 3] & [1, 1, 6] \\
8 & [2, 2, 2, 2] & [1, 1, 4] \\
12 & [2, 2, 2, 2] & [1, 1, 6] \\
16 & [2, 2, 4] & [1, 1, 1, 1] \\
16.9 & \text{\(\infty\)-marker} & \\
18 & [2, 2, 3] & [1, 1, 4] \\
24 & [2, 2, 2, 2] & [1, 1, 3] \\
25 & [1, 1, 1, 1] & [5] \\
27 & [3, 3] & [1, 1, 1, 1] \\
32 & [4, 4] & [1, 1, 1, 1] \\
\hline
\end{array}
\]

Note that we are getting many of the small \( N = 2^a 3^b 5^c \).
## Mobile degree four special HGMs with small $N$

<table>

Note that $(2, 0, 0, 2)$ is hard to make from either algebraic geometry or automorphic representations, and this is perhaps the “source” of the large conductors.
The explicit formula lets me numerically resolve two questions I asked in my October 19 lecture. Here are the relevant parts of that lecture.

The motive $M = H([2^{16}], [1^{16}], 1)$ has Hodge vector $(1, 1, 1, 1, 1, 1, 0, 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, 0)$, a certified-to-10-digits $\Lambda(M, s)$, with conductor $2^{15}$, sign 1, order of central vanishing 2, and $L''(M, 8) \approx 7.851654518$.

The first two Frobenius polynomials (two seconds and thirty seconds):

\[
F_3(x) = (1 - 268 \cdot 3x + 204193 \cdot 3^4 x^2 - 1001800 \cdot 3^9 x^3 + 204193 \cdot 3^{19} x^4 - 268 \cdot 3^{31} x^5 + 3^{45} x^6) \\
(1 + 2992 \cdot x + 39116 \cdot 3^4 x^2 - 7596496 \cdot 3^6 x^3 - 203836426 \cdot 3^{12} x^4 \\
-7596496 \cdot 3^{21} x^5 + 39116 \cdot 3^{34} x^6 + 2992 \cdot 3^{45} x^7 + 3^{60} x^8)
\]

\[
F_5(x) = (1 + 1614 \cdot 5^3 x + 28284579 \cdot 5^4 x^2 + 1394686516 \cdot 5^9 x^3 + 28284579 \cdot 5^{19} x^4 + 1614 \cdot 5^{33} x^5 + 5^{45} x^6) \\
(1 - 41208 \cdot x - 44999364 \cdot 5^3 x^2 - 22376708712 \cdot 5^6 x^3 + 3926679014806 \cdot 5^{12} x^4 \\
-22376708712 \cdot 5^{21} x^5 - 44999364 \cdot 5^{33} x^6 - 41208 \cdot 5^{45} x^7 + 5^{60} x^8)
\]
The splitting $M = M_6 \oplus M_8$ is known a priori from a joint symmetry $t \leftrightarrow 1/t$ and $2 \leftrightarrow 1$. The Hodge vectors of the summands are

$$h_6 = (0, 1, 0, 1, 0, 1, 0, 0, 0, 1, 0, 1, 0, 1, 0),$$

$$h_8 = (1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1).$$

The two Frobenius polynomials suffice to prove that the motivic Galois group of the two factors are $GSp_6$ and $GSp_8$.

**Q1.** Since $L_2(M, s) = 1$, there are only two possibilities for $(\text{cond}(M_6), \text{cond}(M_8))$, namely $(2^6, 2^9)$ or $(2^7, 2^8)$. Which is it?

**Q2.** There are only three possibilities for $(\text{rank}(M_6), \text{rank}(M_8))$, namely $(2, 0)$, $(1, 1)$, or $(0, 2)$. Which one is correct?
Calculating and factoring a few $F_p(x)$

We have tons of $c_p^e$. However, to get the decomposition $c_p^e = c_p^6 + c_p^8$, even for just $e = 1$, we need to factor all of $F_p(x)$. The next two (8 minutes and 2.5 hours):

\[
F_7(x) = \left(1 + 248232 \cdot 7x + 36864645 \cdot 7^4 x^2 - 12114440144 \cdot 7^9 x^3 + 36864645 \cdot 7^{19} x^4 + 248232 \cdot 7^{31} x^5 + 7^{45} x^6 \right) \cdot \left(1 + 667104x + 92084011804 \cdot 7^2 x^2 + 107704347009888 \cdot 7^6 x^3 + 216772203079210 \cdot 7^{13} x^4 + 107704347009888 \cdot 7^{21} x^5 + 92084011804 \cdot 7^{32} x^6 + 667104 \cdot 7^{45} x^7 + 7^{60} x^8 \right)
\]

\[
F_{11}(x) = \left(1 - 883812 \cdot 11x + 86399921193 \cdot 11^4 x^2 - 113266524342552 \cdot 11^9 x^3 + 86399921193 \cdot 11^{19} x^4 - 883812 \cdot 11^{31} x^5 + 11^{45} x^6 \right) \cdot \left(1 + 34438544x + 7563161639884 \cdot 11^2 x^2 - 5931371880123984 \cdot 11^7 x^3 + 1164681420132811670 \cdot 11^{12} x^4 - 5931371880123984 \cdot 11^{22} x^5 + 7563161639884 \cdot 11^{32} x^6 + 34438544 \cdot 11^{45} x^7 + 11^{60} x^8 \right)
\]
Getting a few zeros of \( \Lambda(s, M) \)

Calculating \( \Lambda(s, M) \) with enough precision to make each contribution to \( \log N \) very likely accurate to five decimal places gives

\[
\gamma_1 \approx 1.93195000805, \quad \gamma_2 \approx 3.00559765, \quad \gamma_3 \approx 3.61679, \quad \ldots
\]

The Hardy Z-function on \([0, 7]\) is

![Graph of the Hardy Z-function on [0, 7]](image)

Note that this calculation does not give any hints as to the desired factorization \( Z(t) = Z_6(t)Z_8(t) \). In other words, we do not know which motive a given \( t_i \) belongs to.
Applying the explicit formula to $M_6$ and $M_8$

Plugging into the explicit formula, dividing all terms by log 2 for greater clarity, and keeping track of partial sums:

New challenges

Because their Hodge vectors are so spread, the conductors are actually not that small. Namely, the bound $N_{2,h_6} \approx 1.96$ and even the marker $N_{\infty,h_6} \approx 11.29$ are much less than $2^6 = 64$, while $N_{2,h_8} \approx 2.91$ and $N_{\infty,h_8} \approx 29.4$ are likewise much less than $2^9 = 512$.

Problem 1. *Find motives which have these Hodge numbers but smaller conductor.*

Problem 2. *Improve the general hypergeometric theory so that one can calculate directly on the summands of $M([2^d],[1^d], \pm 1)$. Then one could work analytically for $d$ up through around 30, explicitly seeing factorizations like $M = M_{13} \oplus M_{15}$.
